Package ‘bbmle’

February 19, 2015

Title Tools for general maximum likelihood estimation
Version 1.0.17
Author Ben Bolker <bolker@mcmaster.ca>, R Development Core Team
Maintainer Ben Bolker <bolker@mcmaster.ca>
Depends R (>= 3.0.0), stats4, methods
Imports stats, numDeriv, lattice, MASS
Suggests emdbook, rms, ggplot2, RUnit, MuMIn, AICcmodavg, Hmisc, optimx (>= 2013.8.6), knitr, testthat
VignetteBuilder knitr
BuildVignettes yes
Description Methods and functions for fitting maximum likelihood models in R. This package modifies and extends the mle classes in the stats4 package.
License GPL

convert profile to data frame

Description

converts a profile of a fitted mle2 object to a data frame

Usage

```r
## S3 method for class 'profile.mle2'
as.data.frame(x, row.names=NULL, optional=FALSE, ...)
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>a profile object</td>
</tr>
<tr>
<td>row.names</td>
<td>row names (unused)</td>
</tr>
<tr>
<td>optional</td>
<td>unused</td>
</tr>
<tr>
<td>...</td>
<td>unused</td>
</tr>
</tbody>
</table>

Value

a data frame with columns

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>param</td>
<td>name of parameter being profiled</td>
</tr>
<tr>
<td>z</td>
<td>signed square root of the deviance difference from the minimum parameter values</td>
</tr>
<tr>
<td>focal</td>
<td>value of focal parameter: redundant, but included for plotting convenience</td>
</tr>
</tbody>
</table>

Author(s)

Ben Bolker
Examples

```r
## use as.data.frame and lattice to plot profiles
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
library(bbmle)
LL <- function(ymax=15, xhalf=6)
- sum(stats::dpois(y, lambda=ymax/(1+x/xhalf), log=TRUE))
## uses default parameters of LL
fit1 <- mle2(LL)
p1 <- profile(fit1)
d1 = as.data.frame(p1)
library(lattice)
xyplot(abs(z)-focal|param,data=d1,
       subset=abs(z)<3,
       type="b",
       xlab="",
       ylab=expression(paste(abs(z),
                           " (square root of ",Delta," deviance")),
       scale=list(x=list(relation="free")))
```

---

**BIC-methods**

*Log likelihoods and model selection for mle2 objects*

**Description**

Various functions for likelihood-based and information-theoretic model selection of likelihood models

**Usage**

```r
## S4 method for signature 'ANY,mle2,logLik'
AICc(object,...,nobs,k=2)
## S4 method for signature 'ANY,mle2,logLik'
qAIC(object,...,k=2)
## S4 method for signature 'ANY,mle2,logLik'
qAICc(object,...,nobs,k=2)
```

**Arguments**

- `object` A logLik or mle2 object
- `...` An optional list of additional logLik or mle2 objects (fitted to the same data set).
- `nobs` Number of observations (sometimes obtainable as an attribute of the fit or of the log-likelihood)
- `k` penalty parameter (nearly always left at its default value of 2)
Details

Further arguments to BIC can be specified in the ... list: delta (logical) specifies whether to include a column for delta-BIC in the output.

Value

A table of the BIC values, degrees of freedom, and possibly delta-BIC values relative to the minimum-BIC model

Methods

logLik signature(object = "mle2"):
Extract maximized log-likelihood.

AIC signature(object = "mle2"):
Calculate Akaike Information Criterion

AICc
signature(object = "mle2"):
Calculate small-sample corrected Akaike Information Criterion

anova signature(object="mle2"):
Likelihood Ratio Test comparison of different models

Note

This is implemented in an ugly way and could probably be improved!

Examples

d <- data.frame(x=0:10,y=c(25, 17, 13, 12, 20, 5, 9, 4, 8))
(fit <- mle2(y~dpois(lambda=ymax/(1+x/xhalf)),
            start=list(ymax=25,xhalf=3),data=d))
(fit2 <- mle2(y~dpois(lambda=(x+1)*slope),
            start=list(slope=1),data=d))
BIC(fit)
BIC(fit,fit2)

---

**call.to.char**

Convert calls to character

Description

Utility function (hack) to convert calls such as y~x to their character equivalent

Usage

call.to.char(x)

Arguments

x a formula (call)
Details
It would be nice if `as.character(y~x)` gave "y~x", but it doesn’t, so this hack achieves the same goal.

Value
a character vector of length 1

Author(s)
Ben Bolker

Examples
```r
as.character(y~x)
call.to.char(y~x)
```

Description
given a list of models, extract the names (or "model n")

Usage
get.mnames(Call)

Arguments
```
Call       a function call (usually a list of models)
```

Value
a vector of model names

Author(s)
Ben Bolker
ICtab  

Compute table of information criteria and auxiliary info

Description

Computes information criteria for a series of models, optionally giving information about weights, differences between ICs, etc.

Usage

```
ICtab(..., type=c("AIC","BIC","AICc","qAIC","qAICc"),
      weights = FALSE, delta = TRUE, base = FALSE,
      logLik=FALSE, sort = TRUE,
      nobs=NULL, dispersion = 1, mnames, k = 2)
AICtab(...,mnames)
BICtab(...,mnames)
AICctab(...,mnames)
## S3 method for class 'ICtab'
print(x,...,min.weight)
```

Arguments

```
...           a list of (logLik or?) mle objects; in the case of AICtab etc., could also include other arguments to ICtab

   type        specify information criterion to use

   base        (logical) include base IC (and log-likelihood) values?

   weights     (logical) compute IC weights?

   logLik      (logical) include log-likelihoods in the table?

   delta       (logical) compute differences among ICs (and log-likelihoods)?

   sort        (logical) sort ICs in increasing order?

   nobs        (integer) number of observations: required for type="BIC" or type="AICc"
               unless objects have a nobs method

   dispersion  overdispersion estimate, for computing qAIC: required for type="qAIC" or type="qAICc"
               unless objects have a "dispersion" attribute

   mnames      names for table rows: defaults to names of objects passed

   k           penalty term (largely unused: left at default of 2)

   x           an ICtab object

   min.weight  minimum weight for exact reporting (smaller values will be reported as "<[min.weight]")
```
Value

A data frame containing:

- **IC**: information criterion
- **df**: degrees of freedom/number of parameters
- **dIC**: difference in IC from minimum-IC model
- **weights**: \(\exp(-\text{dIC}/2)/\text{sum}(\exp(-\text{dIC}/2))\)

Note

1. The print method uses sensible defaults; all ICs are rounded to the nearest 0.1, and IC weights are printed using `format.pval` to print an inequality for values <0.001. 2. The computation of degrees of freedom/number of parameters varies enormously between packages. As long as the df computations for a given set of models is consistent, differences don’t matter, but one needs to be careful with log likelihoods and models taken from different packages. If necessary one can change the degrees of freedom manually by saying `attr(obj,"df")<-df.new`, where `df.new` is the desired number of parameters. 3. Defaults have changed to `sort=TRUE`, `base=FALSE`, `delta=TRUE`, to match my conviction that it rarely makes sense to report the overall values of information criteria.

Examples

```r
set.seed(101)
d <- data.frame(x=1:20,y=rpois(20,lambda=2))
m0 <- glm(y~1,data=d)
m1 <- update(m0,~x)
m2 <- update(m0,~poly(x,2))
AICtab(m0,m1,m2,mnames=LETTERS[1:3])
AICtab(m0,m1,m2,base=TRUE,logLik=TRUE)
AICtab(m0,m1,m2,logLik=TRUE)
AICctab(m0,m1,m2,weights=TRUE)
print(AICctab(m0,m1,m2,weights=TRUE),min.weight=0.1)
```
Maximum Likelihood Estimation

Description

Estimate parameters by the method of maximum likelihood.

Usage

mle2(minuslogl, start, method, optimizer,
    fixed = NULL, data=NULL, subset=NULL,
    default.start=TRUE, eval.only = FALSE, vecpar=FALSE,
    parameters=NULL,
    parnames=NULL,
    skip.hessian=FALSE,
    hessian.opts=NULL,
    use.ginv=TRUE,
    trace=FALSE,
    browse_obj=FALSE,
    transform=NULL,
    gr,
    optimfun,...)
calc_mle2_function(formula,parameters, links, start, parnames, use.deriv=FALSE, data=NULL,trace=FALSE)

Arguments

minuslogl Function to calculate negative log-likelihood, or a formula
start Named list. Initial values for optimizer
method Optimization method to use. See optim.
optimizer Optimization function to use. Currently available choices are "optim" (the default), "nlm", "nlminb", "constrOptim", "optimx", and "optimize". If "optimx" is used, (1) the optimx package must be explicitly loaded with load or require(Warning: Options other than the default may be poorly tested, use with caution.)
fixed Named list. Parameter values to keep fixed during optimization.
data list of data to pass to negative log-likelihood function: must be specified if minuslogl is specified as a formula
subset logical vector for subsetting data (STUB)
default.start Logical: allow default values of minuslogl as starting values?
 eval.only Logical: return value of minuslogl(start) rather than optimizing
vecpar Logical: is first argument a vector of all parameters? (For compatibility with optim.) If vecpar is TRUE, then you should use parnames to define the parameter names for the negative log-likelihood function.
parameters: List of linear models for parameters. \textit{MUST BE SPECIFIED IN THE SAME ORDER as the start vector (this is a bug/restriction that I hope to fix soon, but in the meantime beware)}

links: (unimplemented) specify transformations of parameters

parnames: List (or vector?) of parameter names

gr: gradient function

... Further arguments to pass to optimizer

formula: a formula for the likelihood (see Details)

trace: Logical: print parameter values tested?

browse_obj: Logical: drop into browser() within the objective function?

transform: (stub) list of link functions/parameter transformations ("log"=log/exp, "logit"=plogis/qlogis, etc.)

skip.hessian: Bypass Hessian calculation?

hessian.opts: Options for Hessian calculation, passed through to the \texttt{hessian} function

use.ginv: Use generalized inverse (\texttt{ginv}) to compute approximate variance-covariance

optimfun: user-supplied optimization function. Must take exactly the same arguments and return exactly the same structure as \texttt{optim}.

use.deriv: (experimental, not yet implemented): construct symbolic derivatives based on formula?

Details

The \texttt{optim} optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

The \texttt{minuslogl} argument can also specify a formula, rather than an objective function, of the form \( x \sim \texttt{d} \texttt{distn}(\texttt{param1}, \ldots, \texttt{paramn}) \). In this case \texttt{d} \texttt{distn} is taken to be a probability or density function, which must have (literally) \( x \) as its first argument (although this argument may be interpreted as a matrix of multivariate responses) and which must have a \texttt{log} argument that can be used to specify the log-probability or log-probability-density is required. If a formula is specified, then \texttt{parameters} can contain a list of linear models for the parameters.

If a formula is given and non-trivial linear models are given in \texttt{parameters} for some of the variables, then model matrices will be generated using \texttt{model.matrix}. \texttt{start} can be given:

- as a list containing lists, with each list corresponding to the starting values for a particular parameter;
- just for the higher-level parameters, in which case all of the additional parameters generated by \texttt{model.matrix} will be given starting values of zero (unless a no-intercept formula with \texttt{-1} is specified, in which case all the starting values for that parameter will be set equal)

to be implemented! as an exhaustive (flat) list of starting values (in the order given by \texttt{model.matrix})

The \texttt{trace} argument applies only when a formula is specified. If you specify a function, you can build in your own \texttt{print()} or \texttt{cat()} statement to trace its progress. (You can also specify a value for \texttt{trace} as part of a control list for \texttt{optim}(): see \texttt{optim}.)
The skip.hessian argument is useful if the function is crashing with a "non-finite finite difference value" error when trying to evaluate the Hessian, but will preclude many subsequent confidence interval calculations. (You will know the Hessian is failing if you use method="Nelder-Mead" and still get a finite-difference error.)

If convergence fails, see the manual page of the relevant optimizer (optim by default, but possibly nlm, nlminb, optimx, or constrOptim if you have set the value of optimizer) for the meanings of the error codes/messages.

Value

An object of class "mle2".

Warning

Do not use a higher-level variable named .i in parameters – this is reserved for internal use.

Note

Note that the minuslogl function should return the negative log-likelihood, -log L (not the log-likelihood, log L, nor the deviance, -2 log L). It is the user’s responsibility to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid (e.g. that there are "enough" data and that the estimated parameter values do not lie on the boundary of the feasible parameter space).

If lower, upper, control$parscale, or control$ndeps are specified for optim fits, they must be named vectors.

The requirement that data be specified when using the formula interface is relatively new: it saves many headaches on the programming side when evaluating the likelihood function later on (e.g. for profiling or constructing predictions). Since data.frame uses the names of its arguments as column names by default, it is probably the easiest way to package objects that are lying around in the global workspace for use in mle2 (provided they are all of the same length).

When optimizer is set to "optimx" and multiple optimization methods are used (i.e. the methods argument has more than one element, or all.methods=TRUE is set in the control options), the best (minimum negative log-likelihood) solution will be saved, regardless of reported convergence status (and future operations such as profiling on the fit will only use the method that found the best result).

Examples

```r
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
d <- data.frame(x,y)

## in general it is best practice to use the 'data' argument,
## but variables can also be drawn from the global environment
LL <- function(ymax=15, xhalf=6)
    -sum(stats::dpois(y, lambda=ymax/(1+x/xhalf), log=TRUE))

## uses default parameters of LL
```
(fit <- mle2(LL))
fit1F <- mle2(LL, fixed=list(xhalf=6))
coef(fit1F)
coef(fit1F, exclude.fixed=TRUE)

(fit0 <- mle2(y~dpois(lambda=ymean), start=list(ymean=mean(y)), data=d))
anova(fit0, fit)
summary(fit)
logLik(fit)
vcov(fit)
p1 <- profile(fit)
plot(p1, absVal=FALSE)
confint(fit)

## use bounded optimization
## the lower bounds are really > 0, but we use >=0 to stress-test
## profiling; note lower must be named
(fit1 <- mle2(LL, method="L-BFGS-B", lower=c(ymax=0, xhalf=0)))
p1 <- profile(fit1)
plot(p1, absVal=FALSE)

## a better parameterization:
LL2 <- function(lymax=log(15), lhalf=log(6))
  -sum(stats::dpois(y, lambda=exp(lymax)/(1+x/exp(lhalf)), log=TRUE))
(fit2 <- mle2(LL2))
plot(profile(fit2), absVal=FALSE)
exp(confint(fit2))
vcov(fit2)
cov2cor(vcov(fit2))
mle2(y~dpois(lambda=exp(lymax)/(1+x/exp(lhalf)))),
  start=list(lymax=0, lhalf=0),
  data=d,
  parameters=list(lymax=1, lhalf=1))

## try bounded optimization with nlminb and constrOptim
(fit1B <- mle2(LL, optimizer="nlminb", lower=c(lymax=1e-7, lhalf=1e-7)))
p1B <- profile(fit1B)
confint(p1B)
(fit1C <- mle2(LL, optimizer="constrOptim", ui = c(lymax=1, lhalf=1), ci=2,
  method="Nelder-Mead"))

set.seed(1001)
lymax <- c(0,2)
lhalf <- 0
x <- sort(runif(200))
g <- factor(sample(c("a","b"),200,replace=TRUE))
y <- rnbinom(200,mu=exp(lymax[g])/(1+x/exp(lhalf)),size=2)
d2 <- data.frame(x,g,y)

fit3 <- mle2(y~dnbinom(mu=exp(lymax)/(1+x/exp(lhalf)),size=exp(logk)),
  parameters=list(lymax=g), data=d2,
  start=list(lymax=0,lhalf=0,logk=0))
Class "mle2". Result of Maximum Likelihood Estimation.

Description

This class encapsulates results of a generic maximum likelihood procedure.

Details

When the parameters in the original fit are constrained using `lower` or `upper`, or when `prof.lower` or `prof.upper` are set, and the confidence intervals lie outside the constraint region, `confint` will return `NA`. This may be too conservative – in some cases, the appropriate answer would be to set the confidence limit to the lower/upper bound as appropriate – but it is the most general answer.

(If you have a strong opinion about the need for a new option to `confint` that sets the bounds to the limits automatically, please contact the package maintainer.)

Objects from the Class

Objects can be created by calls of the form `new("mle2", ...)`, but most often as the result of a call to `mle2`.

Slots

call: (language) The call to `mle2`.

call.orig: (language) The call to `mle2`, saved in its original form (i.e. without data arguments evaluated).

coeff: (numeric) Vector of estimated parameters.

data: (data frame or list) Data with which to evaluate the negative log-likelihood function

fullcoeff: (numeric) Fixed and estimated parameters.

vcov: (numeric matrix) Approximate variance-covariance matrix, based on the second derivative matrix at the MLE.

min: (numeric) Minimum value of objective function = minimum negative log-likelihood.

details: (list) Return value from `optim`.

minuslogl: (function) The negative log-likelihood function.

optimizer: (character) The optimizing function used.

method: (character) The optimization method used.

formula: (character) If a formula was specified, a character vector giving the formula and parameter specifications.
Methods

- **coef**: signature(object = "mle2"): Extract coefficients. If exclude.fined=TRUE (it is FALSE by default), only the non-fixed parameter values are returned.
- **confint**: signature(object = "mle2"): Confidence intervals from likelihood profiles, or quadratic approximations, or root-finding.
- **show**: signature(object = "mle2"): Display object briefly.
- **show**: signature(object = "summary.mle2"): Display object briefly.
- **summary**: signature(object = "mle2"): Generate object summary.
- **update**: signature(object = "mle2"): Update fit.
- **vcov**: signature(object = "mle2"): Extract variance-covariance matrix.
- **formula**: signature(object = "mle2"): Extract formula
- **plot**: signature(object = "profile.mle2,missing"): Plot profile.

Examples

```r
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
lowerbound <- c(a=2, b=-0.2)
d <- data.frame(x, y)
fit1 <- mle2(y~dpois(lambda=exp(a+b*x)), start=list(a=0, b=2), data=d,
method="L-BFGS-B", lower=c(a=2, b=-0.2))
(cc <- confint(fit1, quietly=TRUE))
## to set the lower bounds to the limit
na_lower <- is.na(cc[,1])
cc[na_lower,1] <- lowerbound[na_lower]
cc
```

**mle2.options**

*Options for maximum likelihood estimation*

Description

Query or set MLE parameters

Usage

mle2.options(...)

Arguments

... names of arguments to query, or a list of values to set
Details

- optim.methodname of optimization method (see `optim` for choices)
- confintname of confidence-interval: choices are "spline", "uniroot", "hessian" corresponding to spline inversion, attempt to find best answer via uniroot, information-matrix approximation
- optimizeroptimization function to use by default (choices: "optim", "nlm", "nlminb", "constrOptim")

Value

Values of queried parameters, or (invisibly) the full list of parameters

See Also

`mle2-class`

---

**namedrop**

*drop unneeded names from list elements*

Description

goes through a list (containing a combination of single- and multiple-element vectors) and removes redundant names that will make trouble for mle

Usage

`namedrop(x)`

Arguments

- `x` a list of named or unnamed, typically numeric, vectors

Details

examines each element of `x`. If the element has length one and is a named vector, the name is removed; if `length(x)` is greater than 1, but all the names are the same, the vector is renamed

Value

the original list, with names removed/added

Author(s)

Ben Bolker

Examples

```r
x = list(a=c(a=1), b=c(d=1, d=2), c=c(a=1, b=2, c=3))
names(unlist(namedrop(x)))
```
get and set parameter names

Description

Gets and sets the "parnames" attribute on a negative log-likelihood function

Usage

parnames(obj)
parnames(obj) <- value

Arguments

obj    a negative log-likelihood function
value  a character vector of parameter names

Details

The parnames attribute is used by mle2() when the negative log-likelihood function takes a parameter vector, rather than a list of parameters; this allows users to use the same objective function for optim() and mle2()

Value

Returns the parnames attribute (a character vector of parameter names) or sets it.

Author(s)

Ben Bolker

Examples

x <- 1:5
set.seed(1001)
y <- rbinom(5, prob=x/(1+x), size=10)
mfun <- function(p) {
  a <- p[1]
b <- p[2]
  -sum(dbinom(y, prob=a*x/(b+x), size=10, log=TRUE))
}
optim(fn=mfun, par=c(1,1))
parnames(mfun) <- c("a","b")
mle2(minuslogl=mfun, start=c(a=1,b=1), method="Nelder-Mead")
predict-methods

Predicted values from an mle2 fit

Description

Given an mle2 fit and an optional list of new data, return predictions (more generally, summary statistics of the predicted distribution)

Usage

```r
## S4 method for signature 'mle2'
predict(object, newdata=NULL, location="mean", newparams=NULL, ...)

## S4 method for signature 'mle2'
simulate(object, nsim, seed, newdata=NULL, newparams=NULL, ...)

## S4 method for signature 'mle2'
residuals(object, type=c("pearson","response"), location="mean",...)
```

Arguments

- `object` an mle2 object
- `newdata` optional list of new data
- `newparams` optional vector of new parameters
- `location` name of the summary statistic to return
- `nsim` number of simulations
- `seed` random number seed
- `type` residuals type
- `...` additional arguments (for generic compatibility)

Methods

`x = "mle2"` an mle2 fit

Note

For some models (e.g. constant models), `predict` may return a single value rather than a vector of the appropriate length.
Examples

```r
set.seed(1002)
lymax <- c(0, 2)
lhalf <- 0
x <- runif(200)
g <- factor(rep(c("a", "b"), each=100))
y <- rnbinom(200, mu=exp[lymax[g]]/(1+x/exp[lhalf]), size=2)
dat <- data.frame(y, g, x)

fit3 <- mle2(y~dnbinom(mu=exp[lymax]/(1+x/exp[lhalf]), size=exp[logk]),
parameters=list(lymax=g),
start=list(lymax=0, lhalf=0, logk=0),
data=dat)

plot(y-x, col=g)
# true curves
curve(exp(0)/(1+x/exp(0)), add=TRUE)
curve(exp(2)/(1+x/exp(0)), col=2, add=TRUE)
# model predictions
xvec <- seq(0, 1, length=100)
lines(xvec, predict(fit3, newdata=list(g=factor(rep("a", 100), levels=c("a", "b")),
x = xvec)), col=1, lty=2)
lines(xvec, predict(fit3, newdata=list(g=factor(rep("b", 100), levels=c("a", "b")),
x = xvec)), col=2, lty=2)

# comparing automatic and manual predictions
p1 = predict(fit3)
p2A =
with(as.list(coef(fit3)), exp('lymax.(Intercept)')/(1+x[1:100]/exp[lhalf]))
p2B =
with(as.list(coef(fit3)), exp('lymax.(Intercept)'+lymax.gb)/(1+x[101:200]/exp[lhalf]))
all(p1 == c(p2A, p2B))
#
simulate(fit3)
```

Description

Compute likelihood profiles for a fitted model

Usage

```r
# S4 method for signature 'mle2'
profile(fitted, which = 1:p, maxsteps = 100,
alpha = 0.01, zmax = sqrt{qchisq(1 - alpha/2, p)),
del = zmax/5, trace = FALSE, skiperrs=TRUE,
```
profile-methods

```r
std.err,
tol.newmin = 0.001, debug=FALSE,
prof.lower, prof.upper,
skip.hessian = TRUE, try_harder=FALSE, ...)
```

**Arguments**

- `fitted` A fitted maximum likelihood model of class “mle2”
- `which` a numeric or character vector describing which parameters to profile (default is to profile all parameters)
- `maxsteps` maximum number of steps to take looking for an upper value of the negative log-likelihood
- `alpha` maximum (two-sided) likelihood ratio test confidence level to find `zmax`
- `zmax` maximum value of signed square root of deviance difference to find (default value corresponds to a 2-tailed chi-squared test at level `alpha`)
- `del` step size for profiling
- `trace` (logical) produce tracing output?
- `skiperrs` (logical) ignore errors produced during profiling?
- `std.err` Optional numeric vector of standard errors, for cases when the Hessian is badly behaved. Will be replicated if necessary, and NA values will be replaced by the corresponding values from the fit summary
- `tol.newmin` tolerance for diagnosing a new minimum below the minimum deviance estimated in initial fit is found
- `debug` (logical) debugging output?
- `prof.lower` optional vector of lower bounds for profiles
- `prof.upper` optional vector of upper bounds for profiles
- `skip.hessian` skip hessian (defunct?)
- `try_harder` (logical) ignore NA and flat spots in the profile, try to continue anyway?
- `...` additional arguments (not used)

**Details**

See the vignette (vignette("mle2","bbmle")) for more technical details of how profiling is done.

**See Also**

`profile.mle-class`
Description

Definition of the mle2 likelihood profile class, and applicable methods

Usage

```r
## S4 method for signature 'profile.mle2'
plot(x,
 levels, which=1:p, conf = c(99, 95, 90, 80, 50)/100,
 plot.confstr = TRUE,
 confstr = NULL, absVal = TRUE, add = FALSE,
 col.minval="green", lty.minval=2,
 col.conf="magenta", lty.conf=2,
 col.prof="blue", lty.prof=1,
 xlabs=nm, ylab="z",
 onepage=TRUE,
 ask=((prod(par("mfcol")) < length(which)) && dev.interactive() && !onepage),
 show.points=FALSE,
 main, xlim, ylim, ...
)
## S4 method for signature 'mle2'
confint(object, parm, level = 0.95, method,
 trace=FALSE,quietly=!interactive(),
 tol.newmin=0.001,...)
## S4 method for signature 'profile.mle2'
confint(object, parm, level = 0.95, trace=FALSE, ...)
```

Arguments

- `x` An object of class `profile.mle2`
- `object` An object of class `mle2` or `profile.mle2` (as appropriate)
- `levels` levels at which to plot likelihood cutoffs (set by `conf` by default)
- `level` level at which to compute confidence interval
- `which` (numeric or character) which parameter profiles to plot
- `parm` (numeric or character) which parameter(s) to find confidence intervals for
- `method` (character) "spline", "uniroot", or "quad", for spline-extrapolation-based (default), root-finding, or quadratic confidence intervals. By default it uses the value of `mle2.options("confint")` – the factory setting is "spline".
- `trace` trace progress of confidence interval calculation when using 'uniroot' method?
- `conf` (1-alpha) levels at which to plot likelihood cutoffs/confidence intervals
- `quietly` (logical) suppress “Profiling ...” message when computing profile to get confidence interval?
tol.newmin see profile-methods
plot.confstr (logical) plot labels showing confidence levels?
confstr (character) labels for confidence levels (by default, constructed from conf levels)
absVal (logical) plot absolute values of signed square root deviance difference ("V" plot rather than straight-line plot)?
add (logical) add profile to existing graph?
col.minval color for minimum line
lty.minval line type for minimum line
col.conf color for confidence intervals
lty.conf line type for confidence intervals
col.prof color for profile
lty.prof line type for profile
xlabs x labels
ylab y label
onepage (logical) plot all profiles on one page, adjusting par(mfcol) as necessary?
ask (logical) pause for user input between plots?
show.points (logical) show computed profile points as well as interpolated spline?
main (logical) main title
xlim x limits
ylim y limits
... other arguments

Details
The default confidence interval calculation computes a likelihood profile and uses the points therein, or uses the computed points in an existing profile.mle2 object, to construct an interpolation spline (which by default has three times as many points as were in the original set of profile points). It then uses linear interpolation between these interpolated points (!)

Objects from the Class
Objects can be created by calls of the form new("profile.mle2", ...), but most often by invoking profile on an "mle2" object.

Slots
profile: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called z being the signed square root of the deviance, and the others being the parameters with names prefixed by par.vals.
summary: Object of class "summary.mle2". Summary of object being profiled.
profile.mle2-class

Methods

confint signature(object = "profile.mle2"): Use profile to generate approximate confidence intervals for parameters.

plot signature(x = "profile.mle2", y = "missing"): Plot profiles for each parameter.

summary signature(x = "profile.mle2"): Plot profiles for each parameter.

show signature(object = "profile.mle2"): Show object.

See Also

mle2, mle2-class, summary.mle2-class

Examples

```r
x <- seq(0, 10, length = 11)
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
d <- data.frame(x, y)
## we have a choice here: (1) don't impose boundaries on the parameters,
## put up with warning messages about NaN values:
fit1 <- mle2(y ~ dpois(lambda = ymax/(1+x/xhalf)),
            start = list(ymax = 1, xhalf = 1),
            data = d)
plot(fit1)
confint(fit1) ## recomputes profile

## alternatively, we can use box constraints to keep ourselves
## to positive parameter values ...
fit2 <- update(fit1, method = "bobyqa", lower = c(ymax = 0.001, xhalf = 0.001))
p2 <- profile(fit2)
plot(p2)
confint(fit2) ## now we get a warning

## bobyqa is a better-behaved bounded optimizer ...
## BUT recent (development, 2012.5.24) versions of
## optimx no longer allow single-parameter fits!
## Not run:
if (require(optimx)) {
  fit3 <- update(fit1, optimizer = "optimx",
                method = "bobyqa", lower = c(ymax = 0.001, xhalf = 0.001))
p3 <- profile(fit3)
plot(p3)
confint(p3)
}

## End(Not run)
```
relist2

reconstruct the structure of a list

Description
reshapes a vector according to a list template

Usage
relist2(v, l)

Arguments
v vector, probably numeric, of values to reshape
l template list giving structure

Details
attempts to coerce v into a list with the same structure and names as l

Value
a list with values corresponding to v and structure corresponding to l

Author(s)
Ben Bolker

Examples
l = list(b=1, c=2:5, d=matrix(1:4, nrow=2))
relist2(1:9, l)

sbinom

Abstract definitions of distributions

Description
Functions returning values for summary statistics (mean, median, etc.) of distributions

Usage
sbeta(shape1, shape2)
sbetabinom(size, prob, theta)
sbinom(size, prob)
snbinom(size, prob, mu)
snorm(mean, sd)
spois(lambda)
**sbinom**

**Arguments**

- **prob**: probability as defined for `dbinom`, `dnbinom`, or beta-binomial distribution (dbetabinom in the emdbook package)
- **size**: size parameter as defined for `dbinom` or `dbetabinom` in the emdbook package, or size/overdispersion parameter as in `dnbinom`
- **mean**: mean parameter as defined for `dnorm`
- **mu**: mean parameter as defined for `dnbinom`
- **sd**: standard deviation parameter as defined for `dnorm`
- **shape1**: shape parameter for `dbeta`
- **shape2**: shape parameter for `dbeta`
- **lambda**: rate parameter as defined for `dpois`
- **theta**: overdispersion parameter for beta-binomial (see `dbetabinom` in the emdbook package)

**Value**

- **title**: name of the distribution
- **[parameters]**: input parameters for the distribution
- **mean**: theoretical mean of the distribution
- **median**: theoretical median of the distribution
- **mode**: theoretical mode of the distribution
- **variance**: theoretical variance of the distribution
- **sd**: theoretical standard deviation of the distribution

**Note**

These definitions are tentative, subject to change as I figure this out better. Perhaps construct functions that return functions? Strip down results? Do more automatically?

**Author(s)**

Ben Bolker

**See Also**

`dbinom`, `dpois`, `dnorm`, `dnbinom`

**Examples**

sbinom(prob=0.2, size=10)
snbincum(mu=2, size=1.2)
slice

Calculate likelihood "slices"

Description
Computes cross-section(s) of a multi-dimensional likelihood surface

Usage
slice(x, dim=1, ...)
sliceOld(fitted, which = 1:p, maxsteps = 100,
    alpha = 0.01, zmax = sqrt(qchisq(1 - alpha/2, p)),
    del = zmax/5, trace = FALSE,
    tol.newmin=0.001, ...)
slice1D(params,fun,nt=101,lower=-Inf,
    upper=Inf,verbose=TRUE,...)
slice2D(params,fun,nt=31,lower=-Inf,
    upper=Inf,
    cutoff=10,verbose=TRUE,...)
slicetrans(params, params2, fun, extend=0.1, nt=401,
    lower=-Inf, upper=Inf)

Arguments
x a fitted model object of some sort
dim dimensionality of slices (1 or 2)
params a named vector of baseline parameter values
params2 a vector of parameter values
fun an objective function
nt (integer) number of slice-steps to take
lower lower bound(s) (stub?)
upper upper bound(s) (stub?)
cutoff maximum increase in objective function to allow when computing ranges
extend (numeric) fraction by which to extend range beyond specified points
verbose print verbose output?
fitted A fitted maximum likelihood model of class “mle2”
which a numeric or character vector describing which parameters to profile (default is to profile all parameters)
maxsteps maximum number of steps to take looking for an upper value of the negative log-likelihood
alpha maximum (two-sided) likelihood ratio test confidence level to find
zmax maximum value of signed square root of deviance difference to find (default value corresponds to a 2-tailed chi-squared test at level alpha)
slice

\begin{verbatim}
del              step size for profiling
trace            (logical) produce tracing output?
tol.newmin       tolerance for diagnosing a new minimum below the minimum deviance estimated in initial fit is found
...              additional arguments (not used)
\end{verbatim}

Details

Slices provide a lighter-weight way to explore likelihood surfaces than profiles, since they vary a single parameter rather than optimizing over all but one or two parameters.

slice is a generic method

slice1D creates one-dimensional slices, by default of all parameters of a model

slice2D creates two-dimensional slices, by default of all pairs of parameters in a model

slicetrans creates a slice along a transect between two specified points in parameter space (see calcslice in the emdbook package)

Value

An object of class slice with

\begin{verbatim}
slices a list of individual parameter (or parameter-pair) slices, each of which is a data frame with elements
   var1 name of the first variable
   var2 (for 2D slices) name of the second variable
   x parameter values
   y (for 2D slices) parameter values
   z slice values
   ranges a list (?) of the ranges for each parameter
   params vector of baseline parameter values
   dim 1 or 2

sliceOld returns instead a list with elements profile and summary (see profile.mle2)
\end{verbatim}

Author(s)

Ben Bolker

profile
Examples

```r
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
d <- data.frame(x, y)
fit1 <- mle2(y~dpois(lambda=exp(lymax)/(1+exp(lhalf))),
  start=list(lymax=0,lhalf=0),
  data=d)
s1 <- slice(fit1,verbose=FALSE)
s2 <- slice(fit1,dim=2,verbose=FALSE)
require(lattice)
plot(s1)
plot(s2)
## 'transect' slice, from best-fit values to another point
st <- slice(fit1, params2=c(5,0.5))
plot(st)
```

slice.mle2-class  

likelihood-surface slices

Description

evaluations of log-likelihood along transects in parameter space

Objects from the Class

Objects can be created by calls of the form `new("slice.mle2", ...)`. The objects are similar to likelihood profiles, but don’t involve any optimization with respect to the other parameters.

Slots

- `profile`: Object of class "list". List of slices, one for each requested parameter. Each slice is a data frame with the first column called `z` being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.
- `summary`: Object of class "summary.mle2". Summary of object being profiled.

Methods

- `plot` signature(x = "profile.mle2", y = "missing"): Plot profiles for each parameter.

See Also

`profile.mle2-class`
strwrapx

Wrap strings at white space and + symbols

Description
Extended (hacked) version of strwrap: wraps a string at whitespace and plus symbols

Usage
strwrapx(x, width = 0.9 * getOption("width"), indent = 0,
          exdent = 0, prefix = "", simplify = TRUE,
          parsplit = "\n[ \t\n]*\n", wordsplit = "[ \t\n]")

Arguments
- x: a character vector, or an object which can be converted to a character vector by as.character.
- width: a positive integer giving the target column for wrapping lines in the output.
- indent: a non-negative integer giving the indentation of the first line in a paragraph.
- exdent: a non-negative integer specifying the indentation of subsequent lines in paragraphs.
- prefix: a character string to be used as prefix for each line.
- simplify: a logical. If TRUE, the result is a single character vector of line text; otherwise, it is a list of the same length as x the elements of which are character vectors of line text obtained from the corresponding element of x. (Hence, the result in the former case is obtained by unlisting that of the latter.)
- parsplit: Regular expression describing how to split paragraphs
- wordsplit: Regular expression describing how to split words

Details
Whitespace in the input is destroyed. Double spaces after periods (thought as representing sentence ends) are preserved. Currently, possible sentence ends at line breaks are not considered specially.

Indentation is relative to the number of characters in the prefix string.

Examples
## Read in file 'THANKS'.
x <- paste(readLines(file.path(R.home("doc"), "THANKS")), collapse = "\n")
## Split into paragraphs and remove the first three ones
x <- unlist(strsplit(x, "\n[ \t\n]*\n")[-c(1:3)])
## Join the rest
x <- paste(x, collapse = "\n\n")
## Now for some fun:
writelines(strwrap(x, width = 60))
writelines(strwrap(x, width = 60, indent = 5))
writeLines(strwrap(x, width = 60, exdent = 5))
writeLines(strwrap(x, prefix = "THANKS> "))

## Note that messages are wrapped AT the target column indicated by
## 'width' (and not beyond it).
## From an R-devel posting by J. Hosking <jh910@juno.com>.
x <- paste(sapply(sample(10, 100, rep=TRUE),
               function(x) substring("aaaaaaaaaa", 1, x)), collapse = " ")
sapply(10:40,
       function(m)
       c(target = m, actual = max(nchar(strwrap(x, m)))))

summary.mle2-class  Class "summary.mle2", summary of "mle2" objects

Description

Extract of "mle2" object

Objects from the Class

Objects can be created by calls of the form new("summary.mle2", ...), but most often by
invoking summary on an "mle2" object. They contain values meant for printing by show.

Slots

call: Object of class "language" The call that generated the "mle2" object.
coef: Object of class "matrix". Estimated coefficients and standard errors
m2logl: Object of class "numeric". Minus twice the log likelihood.

Methods

  show signature(object = "summary.mle2"): Pretty-prints object
  coef signature(object = "summary.mle2"): Extracts the contents of the coef slot
